

Async & Await (ES8)

* It is an extension to promises itself.

* Async also returns a promise

* So it's basically syntactic sugar, does the same thing as promises but code looks much more readable.

// with promises [Following do the same thing]

```
performTask(task1)
```

- then() ⇒ PerformTask(task2)
- then() ⇒ PerformTask(task3)
- then() ⇒ PerformTask(task4)

// async await

do some async task inside this function
async function playGame(){

```
const task0 = await performTask(task1)  
await performTask(task2);  
await performTask(task3);  
await performTask(task4);
```

```
}
```

await keyword basically indicates we're waiting for something to give us a response.

Instead of chaining with .then() we're awaiting for every task to perform before next one

Practical example

The fetch() methods that let's you make an API call, is actually a promise, so we can do the following

```
fetch('https://jsonoutput/users')  
  .then(response => response.json())  
  .then(console.log(response))
```

Because fetch is a promise we're able to do
 .then() on it

* Note : - response.json() , this json() to convert to json format is also a promise hence again a .then() after it.

→ Let's convert this to async await

```
async function fetchStudents() {  
  const response = await fetch('https://.....')  
  const data = await response.json()  
  console.log(data);  
}
```

Error handling in async await.

async function fetchStudents() {

try {

await fetch(url)

:

}

catch (error) {

console.log(error)

}

}

→ Error handling with async await can be achieved using try catch block.

Put your fetch call (await) inside try and if any error occurs within try then it will be caught in catch block
